Q: Can I configure the Linux kernel's iptables so that it does not drop all packets on my network? We have a shared 10.10.10.0/24 network segment on our 10.10.10.0/24 network. We are implementing WAN failover for this segment via layer-3 and layer-2 solutions. When these failover

procedures are executed, iptables usually drops all traffic on the failed segment. The process looks like this: Failover from one device to the other. Network routes are propagated through iptables. Packets are sent from one device to the other. Packets arrive at the other device, but no packets are sent back. Packets sent to the other device are dropped. This causes problems for our layer-2 failover device because it assumes that it has connected to the shared network and yet it cannot connect, and then it has no packets to send. I found that adding `-A INPUT -i eth0 -p tcp -d 10.10.10.0/24 -j ACCEPT` works around `2d92ce491b`
