Retinal ganglion cells are characterized by the expression of cell-specific surface molecules encoded by membrane-bound genes. We propose to apply the techniques of recombinant DNA technology in order to identify novel genes that encode cell surface-associated products on retinal ganglion cells and their targets. Degenerate oligonucleotide primers will be synthesized using DNA corresponding to highly conserved protein sequences that are present on the amino-terminal extracellular domains of cell-surface glycoproteins. These DNA sequences will be used as starting materials for PCR amplification with specific primers from cDNA libraries. The consensus sequence of each PCR product will be used to initiate "shotgun" DNA sequencing on both strands. The gene encoding a candidate cell surface glycoprotein will be subcloned and the sequence verified by DNA sequencing. Identification of the membrane-bound protein encoded by the purified gene will be accomplished by constructing a cDNA library of mRNA from retinal ganglion cells. A full-length cDNA sequence will be examined for mRNA that is selectively transcribed, as well as specificity of the transcript with respect to the cell type and animal species. Protein expression will be accomplished by transfecting retinal ganglion cells in culture. The protein produced will be purified from cells by immunoprecipitation and subsequent analysis by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. The subunit structure and relative molecular weight of the protein will be determined by two-dimensional sodium dodecyl sulfate-polyacrylamide gel electrophoresis. The function of the protein will be examined by testing its ability to bind to putative ligands in the extracellular matrix or in other cells. The gene for the ganglion cell surface receptor will be used to screen a bank of DNA from a human fetal brain library for homologous sequences. The resultant isolated cDNA sequence will be used to isolate the corresponding human gene from DNA that has been obtained from a human fetal brain library. Together with the gene

Syrian President Bashar al-Assad said in a televised speech on Sunday that the two remaining "terrorist" rebel-held areas were "completely safe" and that over 2,000 militants were being massed there. "This is the reality: the terrorist organization in Syria - the Takfiri terrorists, the Salafist group and its affiliate groups - is a global terrorist group and all countries must support the fight against them," said Assad. Russia, Syria's most powerful ally, said on Sunday that the government has fully retaken Aleppo, the country's second-largest city, which fell to rebels in 2012 and was then a rebel stronghold before returning to government control in mid-2016. The Russian Defense Ministry said that over the course of the offensive, government forces killed more than 2,000 militants. "The terrorists' last stronghold in Aleppo has been completely liberated," the ministry said in a statement, adding that the operation "once and for all deprived the terrorists of their last place of shelter." Anadolu Agency via Getty Images Children wave a flag from a building damaged by an airstrike in western Aleppo province on October 15, 2016. Aleppo is Syria's largest city and had been divided into rebel and government sectors since late 2012. Syria's war began in 2011 with the brutal repression of largely unarmed anti-government protesters demanding political reform and an end to Assad's rule. In a speech last month, Assad said that the government is preparing to go after the Islamic State of Iraq and the Levant (ISIL, also known as ISIS) group as it continues to lose territory to an U.S.-backed alliance of militias in northern Syria. "We will continue what we have been doing, namely attacking the terrorists everywhere and in every form," Assad said. Idlib province is the last remaining province outside 82138339de
